Photoconductivity in Gold Nanogaps

Andreas Hohenau

Nanooptics Group Institute of Physics University of Graz Austria

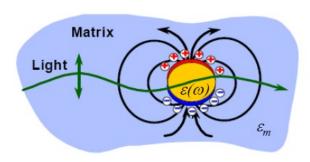

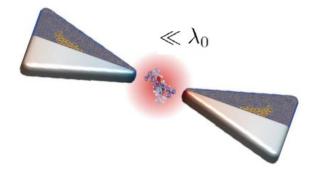

physik.uni-graz.at/en/nanooptics

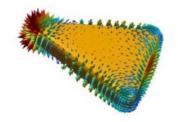

Nano-Optics Research in Graz

Localized Surface Plasmon Resonance

- enhanced local light fields
 - enhanced excitation
 - local refractive index sensing
 - directed electron emission.
- strong and localized absorption
 - local heating with light
- strong scattering
 - enhanced emission
 - cooperative effects in arrays
- strongly curved surfaces
- material properties
- surface/volume ratio
- etc.

Scattering: Collective Effects

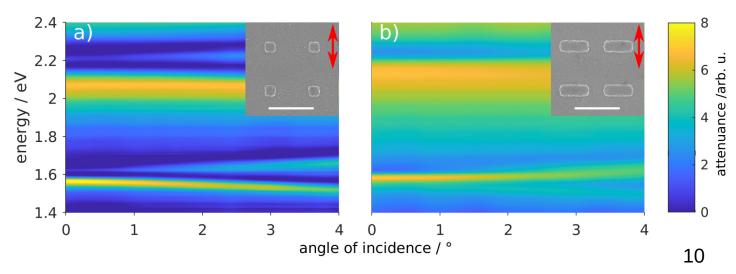

Tunability of Collective Resonances

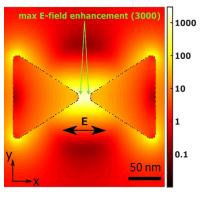

- Narrow and strong attanuance (extinction) peaks promise high field enhancement for surface enhanced spectroscopies
- Peak positions are tunable by array period and angle of incidence

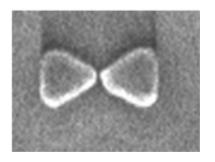

V. Tretnak et al., J. Phys. Chem. C 2020, 124, 3, 2104–2112

Photoconductivity in Gold Nanogaps Motivation

Simulated optical near field enhancement

Electron micrographs of a gold bow-tie

Bow-tie nanoantennas

- Surface plasmon resonances
- High field enhancement
- Strong coupling to fluorophores in the gap

Can we apply a voltage, for example to build sub-wavelength light detectors?

- Add electric contacts
- Place photo-conductor (quantum dots) in the gap
- Observe plasmonic related effects directly in the photocurrent response

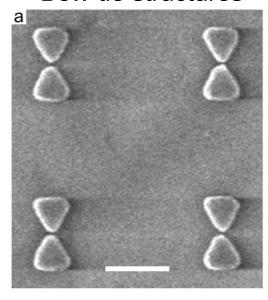

Photoconductivity in Gold Nanogaps Outline

- Electrode structures and quantum dots
- Photocurrent microscopy
- I-V curves
- Polarization effects
- Photocurrent power-law

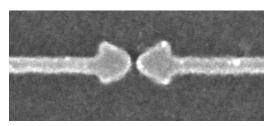

Electrode structures

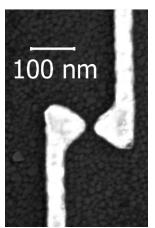

Gold structures on quartz substrate, fabricated by electron beam lithography

Bow-tie structures

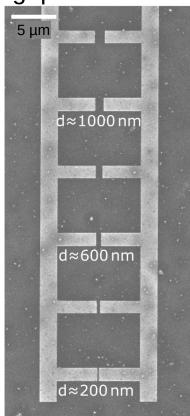

Bow-tie structures with electric connections

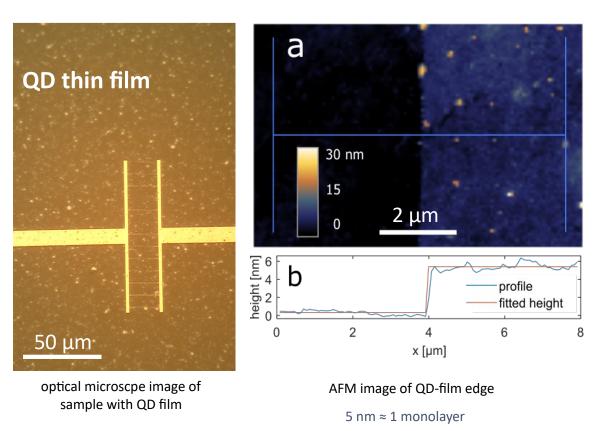

Larger electrode / gap-structures

Quantum Dots

PbS-MAPbl₃ with ~3.2nm core diameter

TEM image

D.N. Dirin et al., J. Am. Chem. Soc. **136**, 6550-6553 (2014).

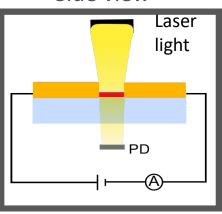

Photocurrent Microscopy

Scanning Photo-Current Microscopy SPCM

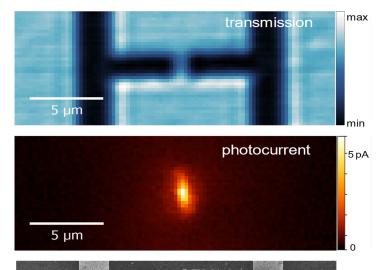

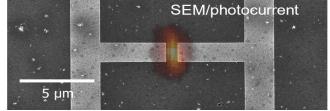

Side view

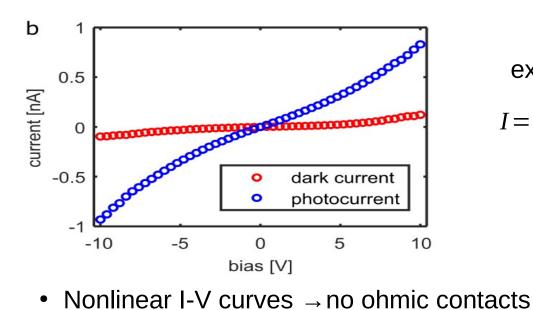

- wavelength-tunable laser, focused (d≈1 μm)
- bias source and ammeter
- piezo scanning stage
- photo-diode to measure transmitted light

SPCM overlapped to a SEM image

I-V-Curves

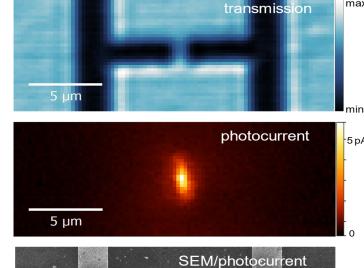

injection from electrodes

Dark current at larger voltages → charge

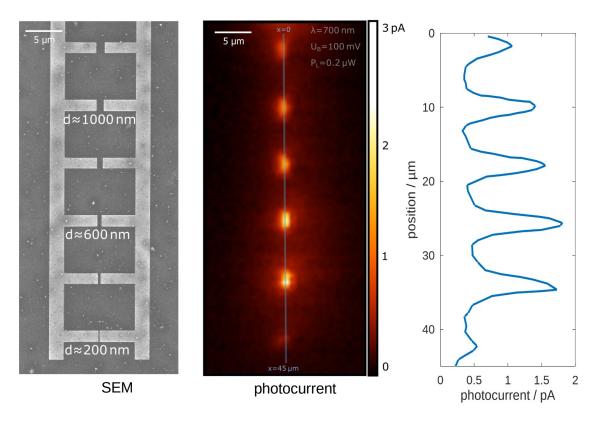

expectation

$$I = \frac{U}{R} = \frac{U \sigma A}{d}$$

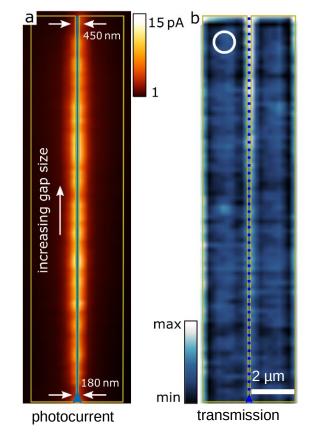

SEM/pho

Photocurrent Gap-Width Dependence 180-450 nm gap width

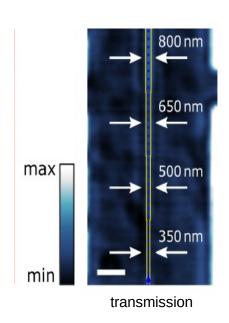

expectation

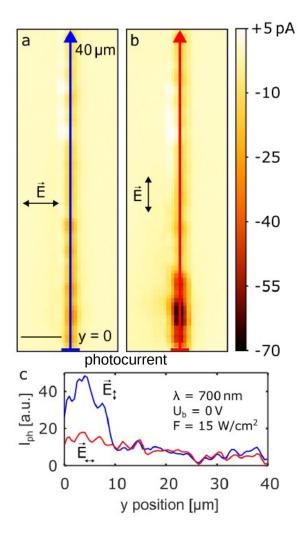

$$I = \frac{U}{R} = \frac{U \sigma A}{d}$$

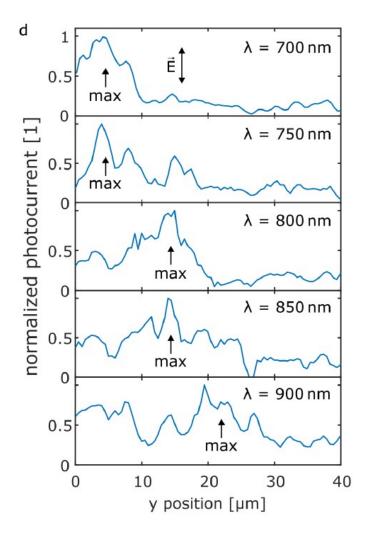

- no homogeneous photoconductor
- exciton quenching by metal bands

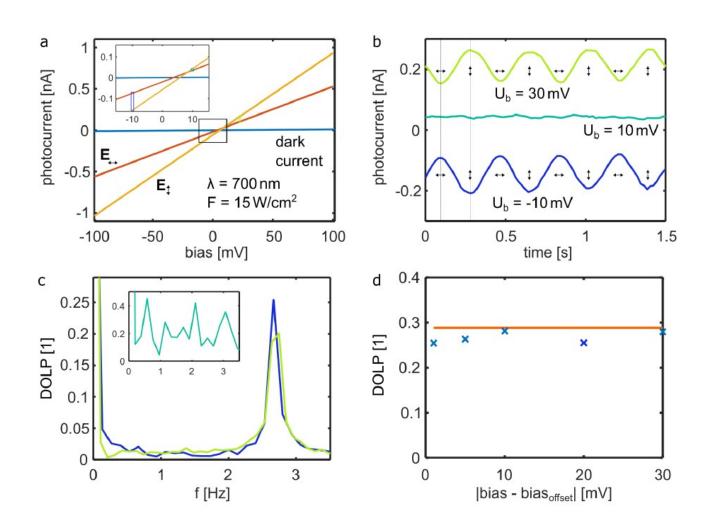

Gap-Width Dependence

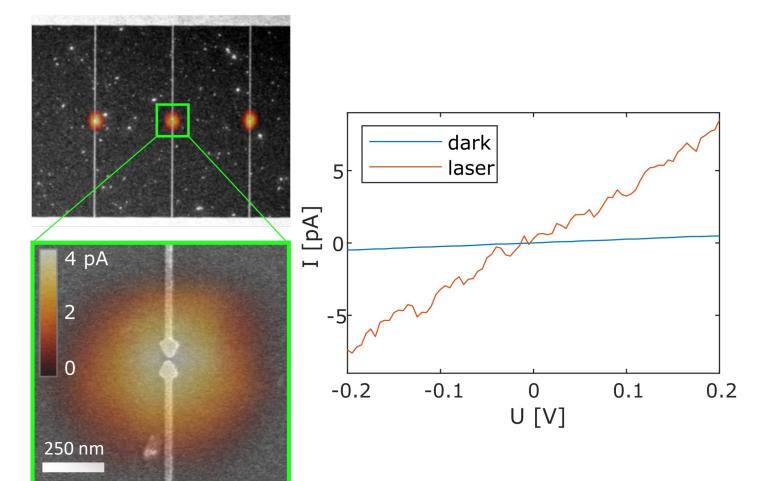

Polarization Effects

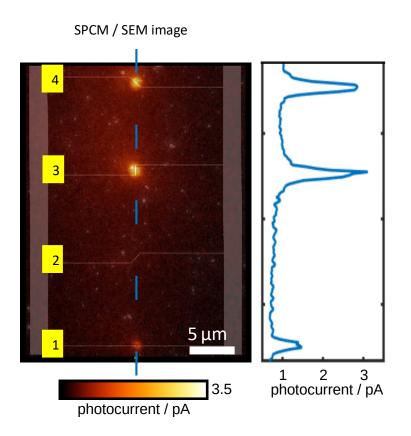

- ~30% polarization anisotropy of photocurrent
- larger photocurrent for polarization parallel to electrode edges
- Photocurrent at zero bias

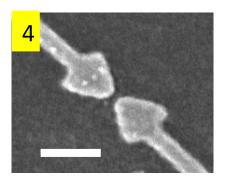

Bow-Tie Structures

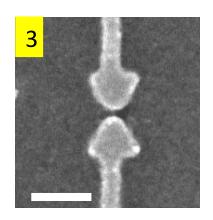

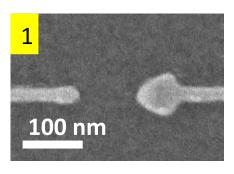

- Reproducible photocurrents from bow-tie structures
- Photocurrent is more noisy than darkcurrent

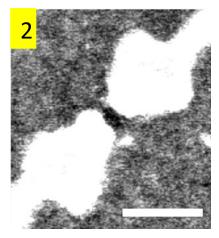

Bow-Tie Structures

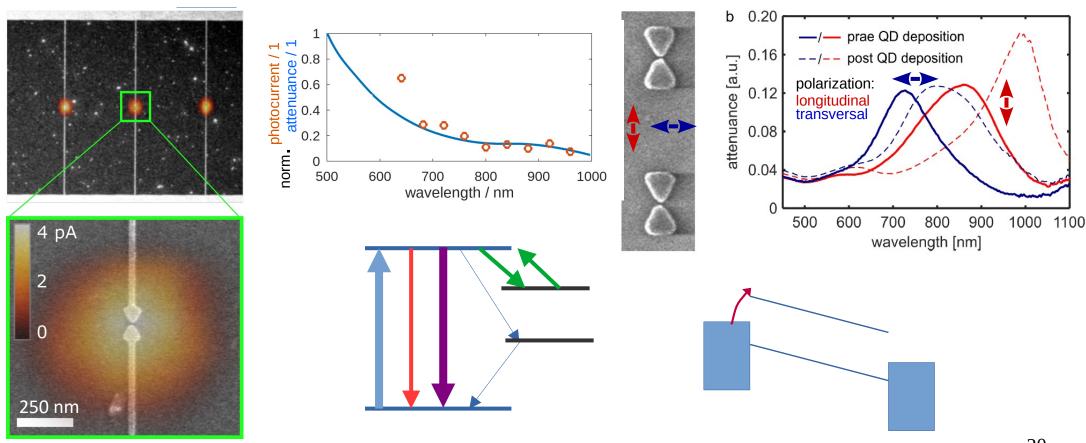

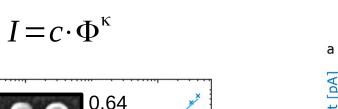

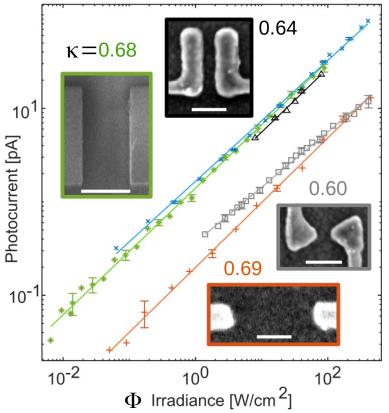

Spectral Response and Polarization Effects in Bow-Tie Structures

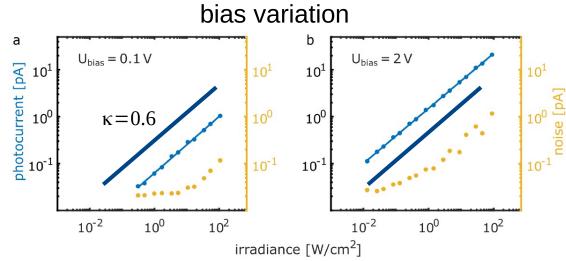

• Polarization anisotropy:~15%; maximum photocurrent for transversal polarization

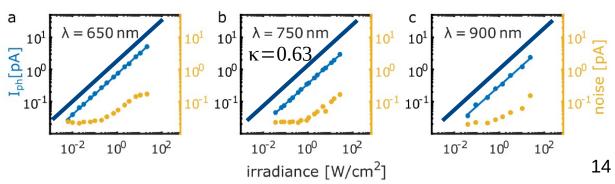

Photocurrent Power-Law

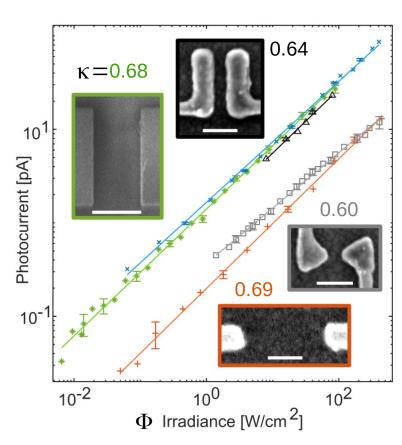

Photocurrent Power-Law

$$I = c \cdot \Phi^{\kappa} = n \mu q U f_{geom}$$

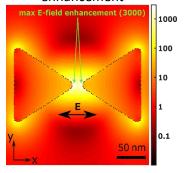

- Photocurrent follows a power law
- Exponents in the range of κ =0.6-0.7
- Sample-to-sample variations $\Delta \kappa = 0.02$
- Some weak influence of electrode geometry

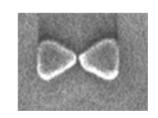

Possible origins of the power law:

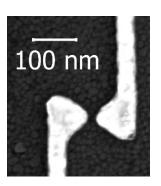

- Trap energy distribution
- Fluctuating percolation paths
- Recombination process dependence on charge carrier density

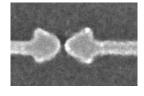

Photoconductivity in Gold Nanogaps Conclusion

Simulated optical near field enhancement

Electron micrographs of bow-tie structures with and without electric contacts

Bow-tie nanoantennas

- Surface plasmon resonances
- High field enhancement
- Strong coupling to fluorophores in the gap

Can we apply a voltage, for example to build sub-wavelength light detectors?

- Add electric contacts
- Place photoconductor (quantum dots) in the gap
- Observe plasmonic related effects directly in the photocurrent response ...not exactly!
- Very stable system no degradation over month
- other potential use of electric contacts?

Photoconductivity in Gold Nanogaps

Conclusion

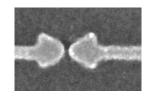

polarization: longitudinal transversal

Bow-tie nanoantennas

- Surface plasmon resonances
- High field enhancement
- Strong coupling to fluorophores in the gap

100 nm

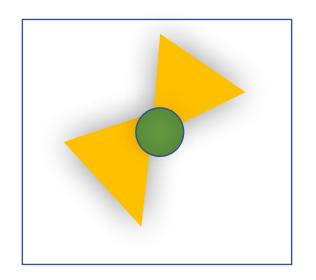

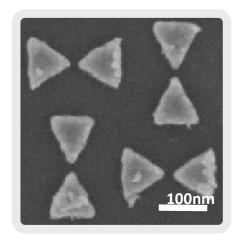

Electron micrographs of bow-tie structures with and without electric contacts

Can we apply a voltage, for example to build sub-wavelength light detectors?

- Add electric contacts
- Place photoconductor (quantum dots) in the gap
- Observe plasmonic related effects directly in the photocurrent response ...not exactly!
- Very stable system no degradation over month
- other potential use of electric contacts?

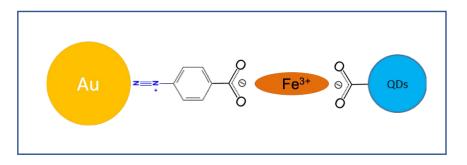

Perspective: regio-selective deposition of QDs in the location of hot-spots

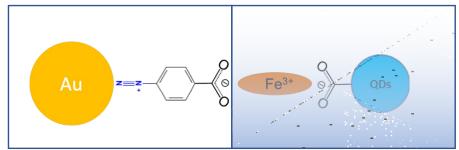

Au bowties fabricated by EBL

Multi-step strategy

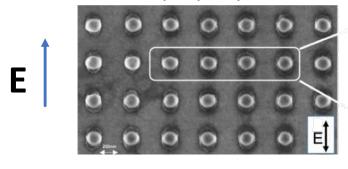

Diazonium salt: DCOOH Cationic iron in solution Fe3⁺ QD negatively charged

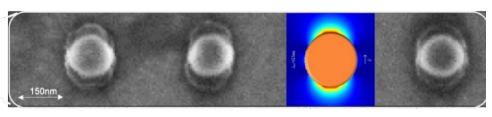

Step 1: regio-selective deposition of QDs in the location of hot-spots

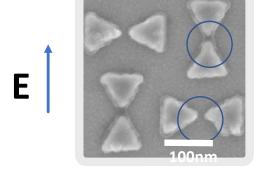

Diazonium salt: DCOOH

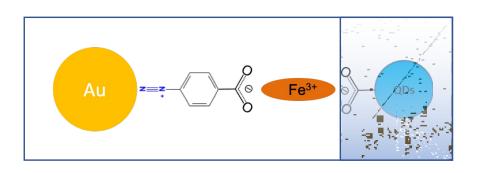

Strategy: hot electron generation: regio-selective grafting uder LSP excitation of poly-aryl films derived from diazonium salts

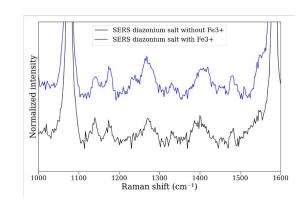

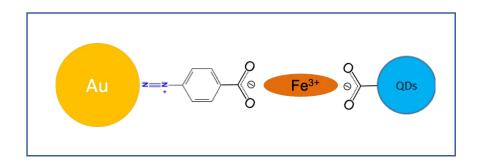

Step 2: addition of Fe3⁺ in the location of hot-spots

SERS spectrum of DCOO-in presence of Fe³⁺

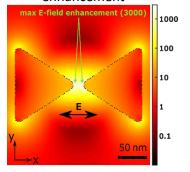

Step 3: addition of QDs negatively charged in the location of hot-spots (in progress)
